Algebraic Datatypes Types

### Examples

In OCaml:

```ocaml
type 'a list =  
  | Nil : 'a list  
  | Cons : 'a * 'a list → 'a list
```

or

```ocaml
type ('leaf, 'node) tree =  
  | Leaf : 'leaf → ('leaf, 'node) tree  
  | Node : ('leaf, 'node) tree * 'node * ('leaf, 'node) tree → ('leaf, 'node) tree
```
Algebraic Data Types

Existential types GADTs

Algebraic Datatypes Types

General case

type $G\vec{\alpha} = \sum_{i\in 1..n} (C_i : \forall \vec{\alpha}. \tau_i \to G\vec{\alpha})$ where $\vec{\alpha} = \bigcup_{i\in 1..n} \text{ftv} (\tau_i)$

In System F, this amounts to declaring (implicit version for conciseness):

- a new type constructor $G$,
- $n$ constructors $C_i : \forall \vec{\alpha}. \tau_i \to G\vec{\alpha}$
- one destructor $d_G : \forall \vec{\alpha}, \gamma. G\vec{\alpha} \to (\tau_1 \to \gamma) \ldots (\tau_n \to \gamma) \to \gamma$
- $n$ reduction rules $d_G (C_i v) v_1 \ldots v_n \rightsquigarrow v_i v$

Exercise

Show that this extension verifies the subject reduction and progress axioms for constants.
Algebraic Datatypes Types

General case

\[ \text{type } G \vec{\alpha} = \sum_{i \in 1..n} (C_i : \forall \vec{\alpha}. \tau_i \rightarrow G \vec{\alpha}) \quad \text{where } \vec{\alpha} = \bigcup_{i \in 1..n} \text{ftv}(\tau_i) \]

Notice that

- All constructors build values of the same type \( G \vec{\alpha} \) and are surjective (all types can be reached)
- The definition may be recursive, i.e. \( G \) may appear in \( \tau_i \)

Algebraic datatypes introduce \textit{iso-recursive types}. 
Algebraic Data Types

- Equi- and iso-recursive types

Existential types

- Implicitly-type existential types passing
- Iso-existential types

Generalized Algebraic Datatypes
Recursive Types

Product and sum types alone do not allow describing *data structures* of *unbounded size*, such as lists and trees.

Indeed, if the grammar of types is $\tau ::= \text{unit} \mid \tau \times \tau \mid \tau + \tau$, then it is clear that every type describes a *finite* set of values.

For every $k$, the type of lists of length at most $k$ is expressible using this grammar. However, the type of lists of unbounded length is not.
Equi- versus iso-recursive types

The following definition is inherently *recursive*:

“A list is either empty or a pair of an element and a list.”

We need something like this:

\[
list \alpha \diamond unit + \alpha \times list \alpha
\]

But what does \(\diamond\) stand for? Is it *equality*, or some kind of *isomorphism*?
Equi- versus iso-recursive types

There are two standard approaches to recursive types, dubbed the *equi-recursive* and *iso-recursive* approaches.

In the equi-recursive approach, a recursive type is *equal* to its unfolding.

In the iso-recursive approach, a recursive type and its unfolding are related via explicit *coercions*.
Equi-recursive types

In the equi-recursive approach, the usual syntax of types:

\[ \tau ::= \alpha \mid F \bar{\tau} \mid \forall \beta. \tau \]

is no longer interpreted inductively. Instead, types are the regular infinite trees built on top of this grammar.
Finite syntax for equi-recursive types

If desired, it is possible to use \textit{finite syntax} for recursive types:

$$\tau ::= \alpha | \mu \alpha. (F \bar{\tau}) | \mu \alpha. (\forall \beta. \tau)$$

We do not allow the seemingly more general $\mu \alpha. \tau$, because $\mu \alpha. \alpha$ is meaningless, and $\mu \alpha. \beta$ or $\mu \alpha. \mu \beta. \tau$ are useless. If we write $\mu \alpha. \tau$, it should be understood that $\tau$ is \textit{contractive}, that is, $\tau$ is a type constructor application or a forall introduction.

For instance, the type of lists of elements of type $\alpha$ is:

$$\mu \beta. (\text{unit} + \alpha \times \beta)$$
Finite syntax for equi-recursive types

In the absence of quantifiers

Each type in this syntax denotes a unique regular tree, sometimes known as its *infinite unfolding*. Conversely, every regular tree can be expressed in this notation (possibly in more than one way).

If one builds a type-checker on top of this finite syntax, then one must be able to *decide* whether two types are *equal*, that is, have identical infinite unfoldings.

This can be done efficiently, either via the algorithm for comparing two DFAs, or by unification. (The latter approach is simpler, faster, and extends to the type inference problem.)

In the presence of quantifiers The situation is more subtle because of $\alpha$-conversion. A canonical form can still be found, so that checking equality and first-order unification on types can still be done in $O(n \log n)$. See [Gauthier and Pottier, 2004].
Finite syntax for equi-recursive types

One can also prove [Brandt and Henglein, 1998] that equality is the least congruence generated by the following two rules:

\[
\text{Fold/Unfold} \quad \mu \alpha. \tau = [\alpha \mapsto \mu \alpha. \tau] \tau
\]

\[
\text{Uniqueness} \quad \tau_1 = [\alpha \mapsto \tau_1] \tau \quad \tau_2 = [\alpha \mapsto \tau_2] \tau
\]

\[
\tau_1 = \tau_2
\]

In both rules, \( \tau \) must be contractive.

This axiomatization does not directly lead to an efficient algorithm for deciding equality, though.

There is also a simple co-inductive definition:

\[
\alpha = \alpha \quad [\alpha \mapsto \mu \alpha.F \bar{\tau}'] \bar{\tau} = [\alpha \mapsto \mu \alpha.F \bar{\tau}] \bar{\tau}'
\]

\[
\mu \alpha.F \bar{\tau} = \mu \alpha.F \bar{\tau}'
\]

\[
\mu \alpha.\forall \beta. \tau = [\alpha \mapsto \mu \alpha.\forall \beta. \tau'] \tau'
\]

Exercise

Show that \( \mu \alpha.A \alpha = \mu \alpha.A \alpha \alpha \) and \( \mu \alpha.AB \alpha = A \mu \alpha.B \alpha \) with both inductive and co-inductive definitions. Can you do it without the Uniqueness rule?
Type soundness for equi-recursive types

In the presence of equi-recursive types, structural induction on types is no longer permitted, but we never used it anyway – in soundness proofs.

We only need it to prove the termination of reduction, which does not hold any longer.

It remains true that $F \vec{\tau}_1 = F \vec{\tau}_2$ implies $\vec{\tau}_1 = \vec{\tau}_2$—this was used in the proof of Subject Reduction.

It remains true that $F_1 \vec{\tau}_1 = F_2 \vec{\tau}_2$ implies $F_1 = F_2$—this was used the proof of Progress.

So, the reasoning that leads to type soundness is unaffected.

(Exercise: prove type soundness for the simply-typed $\lambda$-calculus in Coq. Then, change the syntax of types from Inductive to CoInductive.)
Iso-recursive types

With iso-recursive types, the folding/unfolding is witnessed by an explicit coercion (e.g. as above).

*The uniqueness rule is usually not present (hence, the equality relation is weaker)*.

Encoding iso-recursive types with ADT

The recursive type \( \mu \beta. \tau \) can be represented in System F by introducing a datatype with a unique constructor:

\[
\text{type } G \, \vec{\alpha} = \Sigma (C : \forall \vec{\alpha}. [\beta \mapsto G \, \vec{\alpha}] \tau \to G \, \vec{\alpha}) \quad \text{where } \vec{\alpha} = \text{ftv}(\tau) \setminus \{\beta\}
\]

The constructor \( C \) coerces \([\beta \mapsto G \, \vec{\alpha}] \tau\) to \( G \, \vec{\alpha} \) and the reverse coercion is the function \( \lambda x. d_G x (\lambda y. y) \).

Since this datatype has a unique constructor, pattern matching always succeeds and amounts to the identity. Hence, in \( \llbracket F \rrbracket \), the constructor could be removed: coercions have no computational content.
Records

A record can be defined as

\[ \text{type } G \vec{\alpha} = \Pi_{i \in 1..n} (l_i : \tau_i) \quad \text{where } \vec{\alpha} = \bigcup_{i \in 1..n} \text{ftv}(\tau_i) \]

Exercise

* What are the corresponding declarations in System F?
  * a new type constructor \( G_\Pi \),
  * 1 constructor \( C_\Pi : \forall \vec{\alpha}. \tau_1 \to \ldots \tau_n \to G \vec{\alpha} \)
  * \( n \) destructors \( d_{l_i} : \forall \vec{\alpha}. G \vec{\alpha} \to \tau_i \)
  * \( n \) reduction rules \( d_{l_i}(C_\Pi v_1 \ldots v_n) \rightarrow v_i \)

Can a record also be used for defining recursive types? Show type soundness for records.
Deep pattern matching

In practice, one allows deep pattern matching and wildcards in patterns.

```plaintext
type nat = Z | S of nat
let rec equal n1 n2 = match n1, n2 with
  | Z, Z       → true
  | S m1, S m2 → equal m1 m2
  | _          → false
```

Then, one should check for exhaustiveness of pattern matching.

Deep pattern matching can be compiled away into shallow patterns—or directly compiled to efficient code.

See [Le Fessant and Maranget, 2001; Maranget, 2007]
Regular ADTs

type $G \bar{\alpha} = \sum_{i \in 1..n} (C_i : \forall \bar{\alpha}. \tau_i \rightarrow G \bar{\alpha})$

If all occurrences of $G$ in $\tau_i$ are $G \bar{\alpha}$ then, the ADT is *regular*.

Non-regular ADT’s do not have this restriction.

They usually need polymorphic recursion to be manipulated.

Non regular ADT are heavily used by Okasaki [1999] for implementing purely functional data structures.

Existential types

A frozen application returning a value of type ($\approx$ a thunk)

$$\exists \alpha. (\alpha \to \tau) \times \alpha$$

Type of closures in the environment-passing variant:

$$\llbracket \tau_1 \to \tau_2 \rrbracket = \exists \alpha. ((\alpha \times \llbracket \tau_1 \rrbracket) \to \llbracket \tau_2 \rrbracket) \times \alpha$$

A possible encoding of objects:

$$= \exists \rho. \mu \alpha. \Pi \left( \left\{ (\alpha \times \tau_1) \to \tau'_1; \ldots; (\alpha \times \tau_n) \to \tau'_n \right\} ; \rho \right)$$

$\rho$ describes the state

$\alpha$ is the concrete type of the closure

a tuple...

... that begins with a record...

... of method code pointers...

... and continues with the state

(a tuple of unknown length)
Existential types

One can extend System F with *existential types*, in addition to universals:

\[ \tau ::= \ldots \mid \exists \alpha. \tau \]

As in the case of universals, there are *type-passing* and *type-erasing* interpretations of the terms and typing rules... and in the latter interpretation, there are *explicit* and *implicit* versions.

Let's first look at the *type-erasing* interpretation, with an *explicit* notation for introducing and eliminating existential types.
## Existential types in explicit style

Here is how the existential quantifier is introduced and eliminated:

**Pack**
\[
\Gamma \vdash M : \left[ \alpha \mapsto \tau' \right] \tau
\]
\[
\Gamma \vdash pack_{\tau'}, M \text{ as } \exists \alpha. \tau : \exists \alpha. \tau
\]

**Unpack**
\[
\Gamma \vdash M_1 : \exists \alpha. \tau_1
\]
\[
\Gamma, \alpha, x : \tau_1 \vdash M_2 : \tau_2 \quad \alpha \not\equiv \tau_2
\]
\[
\Gamma \vdash \text{let } \alpha, x = \text{unpack } M_1 \text{ in } M_2 : \tau_2
\]

Anything wrong? The side condition \( \alpha \not\equiv \tau_2 \) is mandatory here to ensure well-formedness of the conclusion.

The side condition may also be written \( \Gamma \vdash \tau_2 \) which implies \( \alpha \not\equiv \tau_2 \), given that the well-formedness of the last premise implies \( \alpha \notin \text{dom}(\Gamma) \).

Note the *imperfect duality* between universals and existentials:

**T\text{Abs}**
\[
\Gamma, \alpha \vdash M : \tau
\]
\[
\Gamma \vdash \Lambda \alpha. M : \forall \alpha. \tau
\]

**T\text{App}**
\[
\Gamma \vdash M : \forall \alpha. \tau
\]
\[
\Gamma \vdash M \tau' : \left[ \alpha \mapsto \tau' \right] \tau
\]
On existential elimination

It would be nice to have a simpler elimination form, perhaps like this:

\[
\Gamma, \alpha \vdash M : \exists \alpha. \tau \\
\Gamma, \alpha \vdash \text{unpack } M : \tau
\]

Informally, this could mean that, if \( M \) has type \( \tau \) for some unknown \( \alpha \), then it has type \( \tau \), where \( \alpha \) is “fresh” ...

Why is this broken?

We could immediately \textit{universally} quantify over \( \alpha \), and conclude that \( \Gamma \vdash \Lambda \alpha . \text{unpack } M : \forall \alpha . \tau \). This is nonsense!

Replacing the premise \( \Gamma, \alpha \vdash M : \exists \alpha. \tau \) by the conjunction \( \Gamma \vdash M : \exists \alpha. \tau \) and \( \alpha \in \text{dom}(\Gamma) \) would make the rule even more permissive, so it wouldn’t help.
On existential elimination

A correct elimination rule must force the existential package to be *used* in a way that does not rely on the value of $\alpha$.

Hence, the elimination rule must have control over the *user* of the package – that is, over the term $M_2$.

\[
\frac{
\text{Unpack} \\
\Gamma \vdash M_1 : \exists \alpha. \tau_1 \\
\Gamma, \alpha; x : \tau_1 \vdash M_2 : \tau_2 \\
\alpha \not= \tau_2 \\
}{\Gamma \vdash \text{let } \alpha, x = \text{unpack } M_1 \text{ in } M_2 : \tau_2}
\]

The restriction $\alpha \not= \tau_2$ prevents writing “let $\alpha, x = \text{unpack } M_1 \text{ in } x$”, which would be equivalent to the unsound “\text{unpack } M” of the previous slide.

The fact that $\alpha$ is bound within $M_2$ forces it to be treated abstractly.

In fact, $M_2$ must be ??? in $\alpha$. 
On existential elimination

In fact, $M_2$ must be \textit{polymorphic} in $\alpha$: the second premise could be:

\[
\Gamma \vdash M_1 : \exists \alpha. \tau_1 \quad \Gamma \vdash \Lambda \alpha. \lambda x : \tau_1. M_2 : \forall \alpha. \tau_1 \rightarrow \tau_2 \quad \alpha \not\# \tau_2
\]

or let $\alpha, x = \text{unpack } M_1 \text{ in } M_2 : \tau_2$

or, if $N_2$ stands for $\Lambda \alpha. \lambda x : \tau_1. M_2$:

\[
\Gamma \vdash M_1 : \exists \alpha. \tau_1 \quad \Gamma \vdash N_2 : \forall \alpha. \tau_1 \rightarrow \tau_2 \quad \alpha \not\# \tau_2
\]

\[
\Gamma \vdash \text{unpack } M_1 \ N_2 : \tau_2
\]

One could even view \(\text{“unpack}_{\exists \alpha. \tau_1}\) as a \textit{constant} with all these types:

\[
\text{unpack}_{\exists \alpha. \tau_1} : \quad (\exists \alpha. \tau_1) \rightarrow (\forall \alpha. (\tau_1 \rightarrow \tau_2)) \rightarrow \tau_2 \quad \alpha \not\# \tau_2
\]

Thus, \[
\text{unpack}_{\exists \alpha. \tau} : \quad \forall \beta. ((\exists \alpha. \tau) \rightarrow (\forall \alpha. (\tau \rightarrow \beta))) \rightarrow \beta
\]

or, better \[
\text{unpack}_{\exists \alpha. \tau} : \quad (\exists \alpha. \tau) \rightarrow \forall \beta. ((\forall \alpha. (\tau \rightarrow \beta)) \rightarrow \beta)
\]

$\beta$ stands for $\tau_2$: it is bound prior to $\alpha$, so it cannot be instantiated to a type that refers to $\alpha$, which reflects the side condition $\alpha \not\# \tau_2$. 

\[
\text{ unpack}_{\exists \alpha. \tau} : \quad (\exists \alpha. \tau) \rightarrow \forall \beta. ((\forall \alpha. (\tau \rightarrow \beta)) \rightarrow \beta)
\]
On existential introduction

\[
\text{PACK} \quad \frac{\Gamma \vdash M : [\alpha \mapsto \tau']\tau}{\Gamma \vdash \text{pack } \tau', M \text{ as } \exists \alpha. \tau : \exists \alpha. \tau}
\]

If desired, "\text{pack}_{\exists \alpha. \tau}" could also be viewed as a constant with all the types:

\[
\text{pack}_{\exists \alpha. \tau} : \quad [\alpha \mapsto \tau']\tau \rightarrow \exists \alpha. \tau
\]

i.e. with polymorphic type:

\[
\text{pack}_{\exists \alpha. \tau} : \quad \forall \alpha. (\tau \rightarrow \exists \alpha. \tau)
\]
Existentials as constants

In System F, existential types can also be presented as constants

\[
\text{pack}_{\exists \alpha. \tau} : \forall \alpha. (\tau \to \exists \alpha. \tau)
\]
\[
\text{unpack}_{\exists \alpha. \tau} : \exists \alpha. \tau \to \forall \beta. ((\forall \alpha. (\tau \to \beta)) \to \beta)
\]

Read:

- for any \( \alpha \), if you have a \( \tau \), then, for some \( \alpha \), you have a \( \tau \);
- if, for some \( \alpha \), you have a \( \tau \), then, (for any \( \beta \),) if you wish to obtain a \( \beta \) out of it, you must present a function which, for any \( \alpha \), obtains a \( \beta \) out of a \( \tau \).

This is somewhat reminiscent of ordinary first-order logic: \( \exists x.F \) is equivalent to, and can be defined as, \( \neg (\forall x. \neg F) \).

Is there an encoding of existential types into universal types?
Encoding existentials into universals

The type translation is \textit{double negation}:
\[
\llbracket \exists \alpha. \tau \rrbracket = \forall \beta. ((\forall \alpha. (\llbracket \tau \rrbracket \rightarrow \beta)) \rightarrow \beta) \quad \text{if } \beta \neq \tau
\]

The term translation is:
\[
\llbracket \text{pack} \exists \alpha. \tau \rrbracket : \forall \alpha. (\llbracket \tau \rrbracket \rightarrow \llbracket \exists \alpha. \tau \rrbracket)
\]
\[
= \Lambda \alpha. \lambda x : \llbracket \tau \rrbracket. \Lambda \beta. \lambda k : \forall \alpha. (\llbracket \tau \rrbracket \rightarrow \beta). k \, \alpha \, x
\]
\[
\llbracket \text{unpack} \exists \alpha. \tau \rrbracket : \llbracket \exists \alpha. \tau \rrbracket \rightarrow \forall \beta. ((\forall \alpha. (\llbracket \tau \rrbracket \rightarrow \beta)) \rightarrow \beta)
\]
\[
= \lambda x : \llbracket \exists \alpha. \tau \rrbracket. x
\]

There is little choice, if the translation is to be type-preserving.

What is the computational content of this encoding?

A \textit{continuation-passing transform}.

This encoding is due to Reynolds [1983], although it has more ancient roots in logic.
The semantics of existential types as constants

$\text{pack}_{\exists \alpha. \tau}$ can be treated as a unary constructor, and $\text{unpack}_{\exists \alpha. \tau}$ as a unary destructor. The $\delta$-reduction rule is:

$$\text{unpack}_{\exists \alpha. \tau_0} (\text{pack}_{\exists \alpha. \tau} \tau' V) \rightarrow \Lambda \beta. \lambda y: \forall \alpha. \tau \rightarrow \beta. y \tau' V$$

It would be more intuitive, however, to treat $\text{unpack}_{\exists \alpha. \tau_0}$ as a binary destructor:

$$\text{unpack}_{\exists \alpha. \tau_0} (\text{pack}_{\exists \alpha. \tau} \tau' V) \tau_1 (\Lambda \alpha. \lambda x: \tau. M) \rightarrow [\alpha \mapsto \tau'] [x \mapsto V] M$$

Remark:

• This does not quite fit in our generic framework for constants, which must receive all type arguments prior to value arguments.
• But our framework could be easily extended.
The semantics of existential types

We extend values and evaluation contexts as follows:

\[
V ::= \ldots \text{pack } \tau', V \text{ as } \tau \\
E ::= \ldots \text{pack } \tau', [] \text{ as } \tau \mid \text{let } \alpha, x = \text{unpack } [] \text{ in } M
\]

We add the reduction rule:

\[
\text{let } \alpha, x = \text{unpack } (\text{pack } \tau', V \text{ as } \tau) \text{ in } M \rightarrow [\alpha \mapsto \tau'] [x \mapsto V] M
\]

Exercise

Show that subject reduction and progress hold.
The semantics of existential types

The reduction rule for existentials destructs its arguments.

Hence, \( \text{let } \alpha, x = \text{unpack } M_1 \text{ in } M_2 \) cannot be reduced unless \( M_1 \) is itself a packed expression, which is indeed the case when \( M_1 \) is a value (or in head normal form).

This contrasts with \( \text{let } x : \tau = M_1 \text{ in } M_2 \) where \( M_1 \) need not be evaluated and may be an application (e.g. with call-by-name or strong reduction strategies).
The semantics of existential types

Exercise

Find an example that illustrates why the reduction of let $\alpha, x = \text{unpack } M_1 \text{ in } M_2$ could be problematic when $M_1$ is not a value.

Need a hint?

Use a conditional Solution

Let $M_1$ be if $M$ then $V_1$ else $V_2$ where $V_i$ is of the form $\text{pack } \tau_i, V_i \text{ as } \exists \alpha. \tau$ and the two witnesses $\tau_1$ and $\tau_2$ differ.

There is no common type for the unpacking of the two possible results $V_1$ and $V_2$. The choice between those two possible results must be made, by evaluating $M_1$, before unpacking.
Is pack too verbose?

Exercise

Recall the typing rule for pack:

\[
\Gamma \vdash M : [\alpha \mapsto \tau']\tau
\]

\[
\Gamma \vdash \text{pack } \tau', M \text{ as } \exists \alpha. \tau : \exists \alpha.\tau
\]

Isn’t the witness type \(\tau'\) annotation superfluous?

- The type \(\tau_0\) of \(M\) is fully determined by \(M\). Given the type \(\exists \alpha.\tau\) of the packed value, checking that \(\tau_0\) is of the form \([\alpha \mapsto \tau']\tau\) is the matching problem for second-order types, which is simple.

- However, the reduction rule need the witness type \(\tau'\). If it were not available, it would have to be computed during reduction. The reduction rule would then not be pure rewriting.

The explicitly-typed language need the witness type for simplicity, while in the surface language, it could be omitted and reconstructed.
- **Algebraic Data Types**
  - Equi- and iso-recursive types

- **Existential types**
  - Implicitly-type existential types passing
  - Iso-existential types

- **Generalized Algebraic Datatypes**
Implicitly-typed existential types

Intuitively, pack and unpack are just type annotations that could be dropped, leaving a let-binding instead of the unpack form.

Hence, the typing rule for implicitly-typed existential types:

\[
\text{Unpack} \quad \begin{array}{c}
\Gamma \vdash a_1 : \exists \alpha. \tau_1 \\
\Gamma, \alpha, x : \tau_1 \vdash a_2 : \tau_2 \\
\alpha \not\equiv \tau_2
\end{array} \quad \Rightarrow \quad \Gamma \vdash \text{let } x = a_1 \text{ in } a_2 : \tau_2
\]

\[
\text{Pack} \quad \Gamma \vdash a : [\alpha \mapsto \tau'] \tau \quad \Rightarrow \quad \Gamma \vdash a : \exists \alpha. \tau
\]

Notice, however, that this let-binding is not typechecked as syntactic sugar for an immediate application!

The semantics of this let-binding is as before:

\[
E ::= \ldots | \text{let } x = E \text{ in } M \quad \text{let } x = V \text{ in } M \rightarrow [x \mapsto V] M
\]

Is the semantics type-erasing?
Implicitly-typed existential types

Yes, it is.

But there is a subtlety! What about the call-by-name semantics?

We chose a call-by-value semantics, but so far, as long as there is no side-effect, we could have chosen a call-by-name semantics (or even perform reduction under abstraction).

In a call-by-name semantics, the let-bound expression is not reduced prior to substitution in the body:

\[
\text{let } x = M_1 \text{ in } M_2 \rightarrow [x \mapsto M_1]M_2
\]

With existential types, this breaks subject reduction!

Why?
Implicitly-typed existential types

Let $\tau_0$ be $\exists \alpha. (\alpha \to \alpha) \to (\alpha \to \alpha)$ and $v_0$ a value of type $bool$. Let $v_1$ and $v_2$ be two values of type $\tau_0$ with incompatible witness types, e.g. $\lambda f. \lambda x. 1 + (f (1 + x))$ and $\lambda f. \lambda x. \text{not} (f (\text{not} x))$.

Let $v$ be the function $\lambda b. \text{if } b \text{ then } v_1 \text{ else } v_2$ of type $bool \to \tau_0$.

$$a_1 = \text{let } x = v \; v_0 \text{ in } x \; (x \; (\lambda y. y)) \quad \to \quad v \; v_0 \; (v \; v_0 \; (\lambda y. y)) = a_2$$

We have $\emptyset \vdash a_1 : \exists \alpha. \alpha \to \alpha$ while $\emptyset \not\vdash a_2 : \tau$.

What happened? The term $a_1$ is well-typed since $v \; v_0$ has type $\tau_0$, hence $x$ can be assumed of type $(\beta \to \beta) \to (\beta \to \beta)$ for some unknown type $\beta$ and $\lambda y. y$ is of type $\beta \to \beta$.

However, without the outer existential type $v \; v_0$ can only be typed with $(\forall \alpha. \alpha \to \alpha) \to \exists \alpha. (\alpha \to \alpha)$, because the value returned by the function need different witnesses for $\alpha$. This is demanding too much on its argument and the outer application is ill-typed.
Implicitly-typed existential types

One could wonder whether the syntax should not allow the implicit introduction of unpacking (instead of requesting a let-binding).

One could argue that if some expression is the expansion of a well-typed let-binding, then it should also be well-typed:

\[
\Gamma \vdash a_1 : \exists \alpha. \tau_1 \\
\Gamma, \alpha, x : \tau_1 \vdash a_2 : \tau_2 \\
\alpha \not\equiv \tau_2
\]

\[
\Gamma \vdash [x \mapsto a_1]a_2 : \tau_2
\]

Comments?

- This rule does not have a logical flavor...
- It fixes the previous example, but not the general case:
  
  *Pick* \(a_1\) *that is not yet a value after one reduction step.*
  
  *Then, after let-expansion, reduce one of the two occurrences of \(a_1\).*
  
  *The result is no longer of the form* \([x \mapsto a_1]a_2\).*
Existential types are trickier than they may appear at first.

The subject reduction property breaks if reduction is not restricted to expressions in head-normal forms.

Unrestricted reduction is still safe because well-typedness may eventually be recovered by further reduction steps—so that progress will never break.
Implicitly-typed existential types

Notice that the CPS encoding of existential types (1) enforces the evaluation of the packed value (2) before it can be unpacked (3) and substituted (4):

\[
\begin{align*}
\llbracket \text{unpack } a_1 (\lambda x. a_2) \rrbracket &= \llbracket a_1 \rrbracket (\lambda x. \llbracket a_2 \rrbracket) \quad (1) \\
&\rightarrow (\lambda k. \llbracket a \rrbracket k) (\lambda x. \llbracket a_2 \rrbracket) \quad (2) \\
&\rightarrow (\lambda x. \llbracket a_2 \rrbracket) \llbracket a \rrbracket \quad (3) \\
&\rightarrow [x \mapsto \llbracket a \rrbracket][a_2] \quad (4)
\end{align*}
\]

In the call-by-value setting, \(\lambda k. \llbracket a \rrbracket k\) would come from the reduction of \(\llbracket \text{pack } a \rrbracket\), i.e. is \((\lambda k. \lambda x. k x) \llbracket a \rrbracket\), so that \(a\) is always a value \(v\).

However, \(a\) need not be a value. What is essential is that \(a_1\) be reduced to some head normal form \(\lambda k. \llbracket a \rrbracket k\).

  - Equi- and iso-recursive types

- **Existential types**
  - Implicitly-type existential types passing
  - Iso-existential types

- **Generalized Algebraic Datatypes**
Iso-existential types in ML

What if one wished to extend ML with existential types?

Full type inference for existential types is undecidable, just like type inference for universals.

However, introducing existential types in ML is easy if one is willing to rely on user-supplied *annotations* that indicate where to pack and unpack.
Iso-existential types in ML

This *iso-existential* approach was suggested by Läufer and Odersky [1994].

Iso-existential types are explicitly *declared*:

\[
D \vec{\alpha} \approx \exists \vec{\beta}. \tau \quad \text{if} \quad \text{ftv}(\tau) \subseteq \vec{\alpha} \cup \vec{\beta} \quad \text{and} \quad \vec{\alpha} \neq \vec{\beta}
\]

This introduces two constants, with the following type schemes:

\[
\begin{align*}
\text{pack}_D & : \forall \vec{\alpha} \vec{\beta}. \tau \rightarrow D \vec{\alpha} \\
\text{unpack}_D & : \forall \vec{\alpha} \vec{\gamma}. D \vec{\alpha} \rightarrow (\forall \vec{\beta}. (\tau \rightarrow \vec{\gamma})) \rightarrow \vec{\gamma}
\end{align*}
\]

(Compare with basic iso-recursive types, where $\vec{\beta} = \emptyset$.)
Iso-existential types in ML

One point has been hidden on the previous slide. The “type scheme:”

$$\forall \vec{\alpha} \gamma. D \vec{\alpha} \to (\forall \vec{\beta}. (\tau \to \gamma)) \to \gamma$$

is in fact not an ML type scheme. How could we address this?

A solution is to make $\text{unpack}_D$ a (binary) primitive construct again (rather than a constant), with an ad hoc typing rule:

\[ \text{UNPACK}_D \]

\[
\frac{
\Gamma \vdash M_1 : D \vec{\tau} \\
\Gamma \vdash M_2 : \forall \vec{\beta}. ([\vec{\alpha} \mapsto \vec{\tau}] \tau \to \tau_2) \quad \vec{\beta} \not\# \vec{\tau}, \tau_2
}{
\Gamma \vdash \text{unpack}_D M_1 M_2 : \tau_2
}\]

where $D \vec{\alpha} \approx \exists \vec{\beta}. \tau$

We have seen a version of this rule in System F earlier; this in an ML version. The term $M_2$ must be polymorphic, which $\text{GEN}$ can prove.
Iso-existential types in ML

Iso-existential types are perfectly compatible with ML type inference. The constant \( \text{pack}_D \) admits an ML type scheme, so it is unproblematic. The construct \( \text{unpack}_D \) leads to this constraint generation rule (see type inference):

\[
\langle \text{unpack}_D \ M_1 \ M_2 : \tau_2 \rangle = \exists \bar{\alpha}. \left( \langle M_1 : D \bar{\alpha} \rangle \ \forall \bar{\beta}. \langle M_2 : \tau \rightarrow \tau_2 \rangle \right)
\]

where \( D \bar{\alpha} \approx \exists \bar{\beta}. \tau \) and, \( \text{w.l.o.g.,} \ \bar{\alpha}\bar{\beta} \neq M_1, M_2, \tau_2. \)

A universally quantified constraint appears where polymorphism is \textit{required}. 
Iso-existent types in ML

In practice, Läuffer and Odersky suggest fusing iso-existent types with algebraic data types.

This can be done in OCaml using GADTs (see last part of the course). The syntax for this in OCaml is:

\[
\text{type } D \vec{\alpha} = \ell : \tau \rightarrow D \vec{\alpha}
\]

where \(\ell\) is a data constructor and \(\vec{\beta}\) appears free in \(\tau\) but does not appear in \(\vec{\alpha}\). The elimination construct is typed as:

\[
\langle \text{match } M_1 \text{ with } \ell \ x \rightarrow M_2 : \tau_2 \rangle = \exists \vec{\alpha}. (\langle M_1 : D \vec{\alpha} \rangle \ \forall \vec{\beta}. \ def \ x : \tau \ in \langle M_2 : \tau_2 \rangle)
\]

where, w.l.o.g., \(\vec{\alpha}\vec{\beta} \neq M_1, M_2, \tau_2\).
An example

Define $\textit{Any} \approx \exists \beta. \beta$. An attempt to extract the raw content of a package fails:

$$\langle \text{unpack}_{\textit{Any}} M_1 (\lambda x. x) : \tau_2 \rangle = \langle M_1 : \textit{Any} \rangle \land \forall \beta. \langle \lambda x. x : \beta \rightarrow \tau_2 \rangle$$

$$\vdash \forall \beta. \beta = \tau_2$$

$$\equiv \text{false}$$

(Recall that $\beta \not\equiv \tau_2$.)
An example

Define

\[ D \alpha \approx \exists \beta. (\beta \to \alpha) \times \beta \]

A client that regards \( \beta \) as abstract succeeds:

\[
\langle \text{unpack}_D \ M_1 \ (\lambda (f, y). f \ y) : \tau \rangle \\
= \exists \alpha. (\langle M_1 : D \alpha \rangle \land \forall \beta. \langle \lambda (f, y). f \ y : ((\beta \to \alpha) \times \beta) \to \tau \rangle) \\
\equiv \exists \alpha. (\langle M_1 : D \alpha \rangle \land \forall \beta. \text{def } f : \beta \to \alpha; y : \beta \text{ in } \langle f \ y : \tau \rangle) \\
\equiv \exists \alpha. (\langle M_1 : D \alpha \rangle \land \forall \beta. \tau = \alpha) \\
\equiv \exists \alpha. (\langle M_1 : D \alpha \rangle \land \tau = \alpha) \\
\equiv \langle M_1 : D \tau \rangle
Existential types calls for universal types!

**Exercise** We reuse the type $D\alpha \approx \exists \beta . (\beta \to \alpha) \times \beta$ of frozen computations. Assume given a list $l$ with elements of type $D\tau_1$.

Assume given a function $g$ of type $\tau_1 \to \tau_2$. Transform the list $l$ into a new list $l'$ of frozen computations of type $D\tau_2$ (without actually running any computation).

$$\text{List.map } (\lambda (z) \text{ let } D(f, y) = z \text{ in } D(((\lambda (z) g (f z)), y))$$

Try generalizing this example to a function that receives $g$ and $l$ and returns $l'$: it does not typecheck...

$$\text{let } \text{lift } g \ l =$$
$$\text{List.map } (\lambda (z) \text{ let } D(f, y) = z \text{ in } D(((\lambda (z) g (f z)), y))$$

In expression `let $\alpha, x = \text{unpack } M_1 \text{ in } M_2`, occurrences of $x$ in $M_2$ can only be passed to external functions (free variables) that are polymorphic so that $x$ does not leak out of its context.
Limits of iso-encodings

Using datatypes for existential and especially universal types is a simple solution to make them compatible with ML, but it comes with some limitations:

- All types must be declared before being used
- Programs become quite verbose, with many constructors that amount to writing type annotations, but in a more rigid way
- In particular, there is no canonical way of representing them. For example, a thunk of type $\exists \beta (\beta \to \text{int}) \times \beta$ could have been defined as `Thunk (succ, 1)` where `Thunk` is either one of

  ```
  type int_thunk = Thunk : ('b -> int) * 'b -> int_thunk
  type 'a thunk = Thunk : ('b -> 'a) * 'b -> 'a thunk
  ```

  but the two types are incompatible.

Hence, other primitive solutions have been considered, especially for universal types.
Uses of existential types

Mitchell and Plotkin [1988] note that existential types offer a means of explaining *abstract types*. For instance, the type:

\[ \exists \text{stack.} \{ \text{empty : stack; push : } \text{int} \times \text{stack} \to \text{stack; pop : stack} \to \text{option (int} \times \text{stack)} \} \]

specifies an abstract implementation of integer stacks.

Unfortunately, it was soon noticed that the elimination rule is too awkward, and that existential types alone do not allow designing *module systems* [Harper and Pierce, 2005].

Montagu and Rémy [2009] make existential types *more flexible* in several important ways, and argue that they might explain modules after all.
Existential types in OCaml

Existential types are available indirectly in OCaml as a degenerate case of GADT and via abstract types and first-class modules.

Via GADT (iso-existential types)

```ocaml
type 'a d = D : ('b -> 'a) * 'b -> 'a d
let freeze f x = D (f, x)
let run (D (f, x)) = f x
```

Via first-class modules (abstract types)

```ocaml
module type D = sig
  type b
  type a
  val f : b -> a
  val x : b
end
let freeze (type u) (type v) f x =
  (module struct
    type b = u
    type a = v
    let f = f
    let x = x
  end : D)
let unfreeze (type u) (module M : D with type a = u) = M.f M.x
```
Contents

  - Implicitly-type existential types passing
  - Iso-existential types

- Generalized Algebraic Datatypes
An introduction to GADTs
Examples

```plaintext
let add (x, y) = x + y in
let not x = if x then false else true in
let body b =
  let step x =
    add (x, if not b then 1 else 2)
in step (step 0))
in body true
```

**Key point** the typechecker refines the types `a` and `b` in each branch

```plaintext
let rec apply : type a b. (a, b) apply -> a -> b = fun f arg ->
  match f with
  | Fadd -> let x, y = arg in x + y
  | Fnot -> let x = arg in if x then false else true
  | Fstep y -> let x = arg in apply Fadd (x, y)
  | Fbody -> let b = arg in
    let step = Fstep (if not b then 1 else 2)
in apply step (apply step 0)
in apply Fbody true
```

Defunctionalization

Introduce a constructor per call site

```plaintext
type ('a, 'b) apply =
  | Fadd : (int * int, int) apply
  | Fnot : (bool, bool) apply
  | Fstep : int -> (int, int) apply
  | Fbody : (bool, int) apply
```
Example

A typed abstract syntax tree

```ml
type 'a expr =
| Int : int → int expr
| Zerop : int expr → bool expr
| If : (bool expr * 'a expr * 'a expr) → 'a expr

let e0 : int expr = (If (Zerop (Int 0), Int 1, Int 2))
```

A typed evaluator (with no failure)

```ml
let rec eval : type 'a . 'a expr → 'a = fun x → match x with
| Int x → x
| Zerop x → eval x > 0
| If (b, e1, e2) → if eval b then eval e1 else eval e2

let b0 = eval e0
```

Exercise
Define a typed abstract syntax tree for the simply-typed lambda-calculus and a typed evaluator.
Example

**Encoding sum types**

```haskell

**type** ('a, 'b) sum = Left of 'a | Right of 'b

``` can be encoded as a product:

```haskell

**type** ('t, 'a, 'b) tag = Ltag : ('a, 'a, 'b) tag | Rtag : ('b, 'a, 'b) tag  
**type** ('a, 'b) prod = Prod : ('t, 'a, 'b) tag * 't → ('a, 'b) prod

```  

```haskell

let sum_of_prod (**type** a b) (p : (a, b) prod) : (a, b) sum =  
  let Prod (t, v) = p in match t with Ltag → Left v | Rtag → Right v

```  

Prod is a single constructor and need not be allocated.

A field common to both cases can be accessed without looking at the tag.

```haskell

**type** ('a, 'b) prod = Prod : ('t, 'a, 'b) tag * 't * bool → ('a, 'b) prod  
let get (**type** a b) (p : (a, b) prod) : bool =  
  let Prod (t, v, s) = p in s

```  

**Exercise**

Can we have a flat representation if 'a is int * int and 'b is bool?
Example

Exercise
Specialize the encoding of sum types to the encoding of 'a list
Example

Generic programming

```ocaml
type 'a ty =
| Tint : int ty
| Tbool : bool ty
| Tlist : 'a ty → ('a list) ty
| Tpair : 'a ty * 'b ty → ('a * 'b) ty

let rec to_string : type a. a ty → a → string =
fun t x → match t with
| Tint → string_of_int x
| Tbool → if x then "true" else "false"
| Tlist t → "[
  " ^ String.concat ";
  (List.map (to_string t) x) ^ "]"
| Tpair (a, b) →
  let u, v = x in "(
  " ^ to_string a u ^ ",
  " ^ to_string b v ^ ")"

let s = to_string (Tpair (Tlist Tint, Tbool)) ([1; 2; 3], true)
```
Other uses of GADTs

GADTs

• May encode data structures invariants, such as the state of an automaton, as illustrated by Pottier and Régis-Gianas [2006] for typechecking LR-parsers.
• They may be used to implement a form of dynamic type (version inspired by the generic printer)
• GADTs can be used to encode type classes, using a technique analogous to defunctionalization [Pottier and Gauthier, 2006].
Reducing GADTs to type equality

All GADTs can be encoded with a single one:

```
type ('a, 'b) eq = Eq : ('a, 'a) eq
```

For instance, generic programming can be redefined as follows:

```
type 'a ty =
    | Tint : ('a, int) eq → 'a ty
    | Tlist : ('a, 'b list) eq * 'b ty → 'a ty
    | Tpair : ('a, ('b * 'c)) eq * 'b ty * 'c ty → 'a ty
```

This declaration is not a GADT, just an existential type!

```
let rec to_string : type a. a ty → a → string = fun t x → match t with
    | Tint Eq → string_of_int x
    | Tlist (Eq, t) → "[" ^ String.concat "; " (List.map (to_string t) x) ^ "]"
    | Tpair (Eq, a, b) →
        let u, v = x in "(" ^ to_string a u ^ ", " ^ to_string b v ^ ")"

let s = to_string (Tpair (Eq, Tlist (Eq, Tint Eq), Tint Eq)) ([1; 2; 3], 0)
```
Reducing GADTs to type equality

All GADTs can be encoded with a single one:

\[
\text{type} \ ('a, 'b) \ eq = \text{Eq} : ('a, 'a) \ eq
\]

For instance, generic programming can be redefined as follows:

\[
\text{type} \ 'a \ ty = \\
| \ Tint : ('a, int) \ eq \rightarrow 'a \ ty \\
| \ Tlist : ('a, 'b \ list) \ eq \ast 'b \ ty \rightarrow 'a \ ty \\
| \ Tpair : ('a, ('b \ast 'c)) \ eq \ast 'b \ ty \ast 'c \ ty \rightarrow 'a \ ty
\]

This declaration is not a GADT, just an existential type!

\[
\text{let rec to_string : type} a. a \ ty \rightarrow a \rightarrow \text{string} = \text{fun} \ t \times \rightarrow \text{match} \ t \ \text{with}
\]

\[
| \ Tint \ Eq \rightarrow \text{string_of_int} \ x \\
| \ Tlist \ (Eq, t) \rightarrow \ldots \\
| \ Tpair \ (Eq, a, b) \rightarrow \ldots
\]

▷ Pattern “Tint Eq” is GADT matching
Reducing GADTs to type equality

All GADTs can be encoded with a single one:

```ocaml
type ('a, 'b) eq = Eq : ('a, 'a) eq
```

For instance, generic programming can be redefined as follows:

```ocaml
type 'a ty =
  | Tint : ('a, int) eq → 'a ty
  | Tlist : ('a, 'b list) eq * 'b ty → 'a ty
  | Tpair : ('a, ('b * 'c)) eq * 'b ty * 'c ty → 'a ty
```

This declaration is not a GADT, just an existential type!

```ocaml
let rec to_string : type a. a ty → a → string = fun t x → match t with
  | Tint p → let p = Eq in string_of_int x
  | Tlist (Eq, t) → ...
  | Tpair (Eq, a, b) → ...
```

▷ Pattern “Tint Eq” is GADT matching
▷ `let p = Eq in..` introduces the equality `a = int` in the current branch
Formalisation of GADTs

We can encode GADTs with type equalities.

We cannot encode type equalities in System F.

They bring something more, namely *local equalities* in the typing context.

We write $\tau_1 \sim \tau_2$ for $(\tau_1, \tau_2) \text{ eq}$

When typechecking an expression

$$E[\text{let } x : \tau_1 \sim \tau_2 = M_0 \text{ in } M] \quad E[\lambda x : \tau_1 \sim \tau_2. M]$$

⚠️ $M$ is typechecked with the assumption that $\tau_1 \sim \tau_2$, i.e. types $\tau_1$ and $\tau_2$ are equivalent, which allows for type conversion within $M$.

⚠️ but $E$ and $M_0$ are typechecked without this assumption.

⚠️ What is learned by an equation remains local to its static scope, and does not extend to its surrounding context (or the rest of the program execution trace).
Fc (simplified)

Add equality coercions to System $F$

Coercions witness type equivalences:

Types

$\tau ::= \ldots \mid \tau_1 \sim \tau_2$

Expressions

$M ::= \ldots \mid \gamma \triangleleft M \mid \gamma$

Coercions are first-class and can be applied to terms.

Typing rules

**Coerce**

$\Gamma \vdash M : \tau_1$  
$\Gamma \vdash \gamma : \tau_1 \sim \tau_2$  

$\Gamma \vdash \gamma \triangleleft M : \tau_2$

**Coercion**

$\Gamma \vdash \gamma : \tau_1 \sim \tau_2$

$\Gamma \vdash \gamma : \tau_1 \sim \tau_2$

**Coabs**

$\Gamma, x : \tau_1 \sim \tau_2 \vdash M : \tau$

$\Gamma \vdash \lambda x : \tau_1 \sim \tau_2. M : \tau$
### Fc (simplified)

Semantics

Coercions should be without computational content

▷ they are just type information, and should be erased at runtime
▷ they should not block redexes
▷ in Fc, we may always push them down inside terms:

\[
\begin{align*}
(\gamma \triangleleft V_1) V_2 & \rightarrow \text{right } \gamma \triangleleft (V_1 (\text{left } \gamma \triangleleft V_2)) \\
(\gamma \triangleleft V) \tau & \rightarrow (\gamma \triangleleft \tau) \triangleleft (V \tau) \\
\gamma_1 \triangleleft (\gamma_2 \triangleleft V) & \rightarrow (\gamma_1; \gamma_2) \triangleleft V
\end{align*}
\]
Semantics

Coercions should be without computational content

Except for coercion abstractions that must stop the evaluation

- Otherwise, one could attempt to reduce $M$ in $\lambda \text{int} \sim \text{bool}. M$ when $M$ is $\text{not} (\text{bool} \triangleleft 0)$, which is well-typed in this context.

- In call-by-value,
  
  $\lambda x : \tau_1 \sim \tau_2. M$ freezes the evaluation of $M$,  
  
  $M \triangleleft \gamma$ resumes the evaluation of $M$.

  Must always be enforced, even with other strategies

- Full reduction at compile time may still be performed, but be aware of stuck programs and treat them as dead branches.
Type soundness

By subject reduction and progress with explicit coercions

Erasing semantics

Important and non obvious.

\[ \gamma \triangleleft M \text{ erases to } M \]
\[ \gamma \text{ erases to } \diamond \]

Slogan that “coercions have 0-bit information”, i.e.
Coercions need not be passed at runtime—but still block the reduction.

Expressions and typing rules

**Coerce**

\[ \frac{\Gamma \vdash M : \tau_1 \quad \Gamma \vdash \tau_1 \sim \tau_2}{\Gamma \vdash M : \tau_2} \]

**Coercion**

\[ \frac{\Gamma \vdash \tau_1 \sim \tau_2}{\Gamma \vdash \diamond : \tau_1 \sim \tau_2} \]

**Coabs**

\[ \frac{\Gamma, x : \tau_1 \sim \tau_2 \vdash M : \tau}{\Gamma \vdash \lambda x : \tau_1 \sim \tau_2. M : \tau} \]
Type soundness

The introduction of type equality constraints in System F has been introduced and formalized by Sulzmann et al. [2007].

Scherer and Rémy [2015] show how strong reduction and confluence can be recovered in the present of possibly uninhabited coercions.

Syntactic proofs
Type soundness

Equality coercions are a small logic of type conversions. This may be enriched with more operations.

A very general form of coercions has been introduced by Cretin and Rémy [2014].

The soundness proof became too cumbersome to be conducted syntactically.

Instead a semantic proof is used, interpreting types as sets of terms (a technique similar to unary logical relations)
Type checking / inference

With explicit coercions, types are fully determined from expressions.

However, the user prefers to leave applications of **Coerce** implicit.

Then types becomes ambiguous: when leaving the scope of an equation: which form should be used, among the equivalent ones?

This must be determined from the context, including the return type, and calls for extra type annotations:

```ml
let rec eval : type a . a expr -> a = fun x -> match x with
    | Int x           -> x  (* x : int, but a = int, should we return x : a? *)
    | Zerop x         -> eval x > 0
    | If (b, e1, e2)   -> if eval b then eval e1 else eval e2
```

In ML, type annotations must be used to tell

- the type of the context
- which datatypes must be typed as GADTs.

In Coq, one must use the return type annotation on matches.
Type inference in ML-like languages with GADTs

Simonet and Pottier [2007] gave a presentation of type inference for GADTs with general typing constraints for ML-like languages.

Pottier and Régis-Gianas [2006] introduced a stratified approach to better propagate constraints from outside to inside GADTs contexts.

Vytiniotis et al. [2011] introduced the outside-in approach, used in Haskell, which restricts type information to flow from outside to inside GADT contexts.

Garrigue and Rémy [2013] introduced the notion of ambivalent types, used in OCaml, to restrict type occurrences that must be considered ambiguous and explicitly specified using type annotations.
(Most titles have a clickable mark “▷” that links to online versions.)
